Technical and Bibliographic Notes / Notes techniques et bibliographiques

The Institute has attempted to obtain the best original copy available for filming. Features of this copy which may be bibliographically unique, which may alter any of the images in the reproduction, or which may significantly change the usual method of filming are checked below.

☐ Coloured covers / Couverture de couleur
☐ Covers damaged / Couverture endommagée
☐ Covers restored and/or laminated / Couverture restaurée et/ou pelliculée
☐ Cover title missing / Le titre de couverture manque
☐ Coloured maps / Cartes géographiques en couleur
☐ Coloured ink (i.e. other than blue or black) / Encre de couleur (i.e. autre que bleue ou noire)
☐ Coloured plates and/or illustrations / Planches et/ou illustrations en couleur
☐ Bound with other material / Relié avec d'autres documents
☐ Only edition available / Seule édition disponible
☐ Tight binding may cause shadows or distortion along interior margin / La reliure serrée peut causer de l'ombre ou de la distorsion le long de la marge intérieure.
☐ Blank leaves added during restorations may appear within the text. Whenever possible, these have been omitted from filming / Il se peut que certaines pages blanches ajoutées lors d'une restauration apparaissent dans le texte, mais, lorsque cela était possible, ces pages n'ont pas été filmées.

☐ Additional comments / Commentaires supplémentaires:

L'institut a microfilmé le meilleur exemplaire qu'il lui a été possible de se procurer. Les détails de cet exemplaire qui sont peut-être uniques du point de vue bibliographique, qui peuvent modifier une image reproduite, ou qui peuvent exiger une modification dans la méthode normale de filmage sont indiqués ci-dessous.

☐ Coloured pages / Pages de couleur
☐ Pages damaged / Pages endommagées
☐ Pages restored and/or laminated / Pages restaurées et/ou pelliculées
☐ Pages discoloured, stained or foxed / Pages décolorées, tachetées ou piquées
☐ Pages detached / Pages détachées
☐ Showthrough / Transparence
☐ Quality of print varies / Qualité inégale de l'impression
☐ Includes supplementary material / Comprend du matériel supplémentaire
☐ Pages wholly or partially obscured by errata slips, tissues, etc., have been refilmed to ensure the best possible image / Les pages totalement ou partiellement obscurcies par un feuillet d'errata, une peurle, etc., ont été filmées à nouveau de façon à obtenir la meilleure image possible.
☐ Opposing pages with varying colouration or discolourations are filmed twice to ensure the best possible image / Les pages s'opposant ayant des colorations variables ou des décolorations sont filmées deux fois afin d'obtenir la meilleure image possible.

This item is filmed at the reduction ratio checked below / Ce document est filmé au taux de réduction indiqué ci-dessous.

The copy filmed here has been reproduced thanks to the generosity of:

Library
Agriculture Canada

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shall contain the symbol \( 
\longrightarrow \) (meaning “CONTINUED”), or the symbol \( \nabla \) (meaning “END”), whichever applies.

Maps, plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:

1 2 3

4 5 6

L'exemplaire filmé fut reproduit grâce à la générosité de:

Bibliothèque
Agriculture Canada

Les images suivantes ont été reproduites avec le plus grand soin, compte tenu de la condition et de la netteté de l'exemplaire filmé, et en conformité avec les conditions du contrat de filmage.

Les exemplaires originaux dont la couverture en papier est imprimée sont filmés en commençant par le premier plat et en terminant soit par la dernière page qui comporte une empreinte d'impression ou d'illustration, soit par le second plat, selon le cas. Tous les autres exemplaires originaux sont filmés en commençant par la première page qui comporte une empreinte d'impression ou d'illustration et en terminant par la dernière page qui comporte une telle empreinte.

Un des symboles suivants apparaîtra sur la dernière image de chaque microfiche, selon le cas: le symbole \( \longrightarrow \) signifie “A SUIVRE”, le symbole \( \nabla \) signifie “FIN”.

Les cartes, planches, tableaux, etc., peuvent être filmés à des taux de réduction différents. Lorsque le document est trop grand pour être reproduit en un seul cliché, il est filmé à partir de l'angle supérieur gauche, de gauche à droite, et de haut en bas, en prenant le nombre d'images nécessaire. Les diagrammes suivants illustrent la méthode.
SPECIAL REPORT

ON

SARCOSPORIDIAE

AND THEIR ASSOCIATION WITH

"LOCO" DISEASE AND DOURINE

BY

E. A. WATSON, V.S.,
Assistant Pathologist
In charge Experimental Station, Lethbridge, Alberta.

Published by order of the Hon. SYDNEY A. FISHER, Minister of Agriculture, Ottawa, Ont.

October, 1908
To the Honourable
The Minister of Agriculture.

Sir,—I beg to transmit herewith a bulletin, being a study of ‘Sarcosporidiae’ and their association with ‘Loco’ disease and Dourine. The investigation on this subject has been conducted by E. A. Watson, V.S., assistant pathologist in charge of the experimental station at Lethbridge, Alberta. I recommend that this be printed for distribution.

I have the honour to be, sir,
Your obedient servant,

J. G. RUTHERFORD.
Veterinary Director General.
Sarcosporidiosis.

A contribution on, with especial reference to its associations with 'Loco' disease and Dourine, and the possibility of mistaking the spores of Sarcocystis for certain so-called developmental forms of trypanosomata.

Although Sarcosporidium are of common occurrence in the musculature of domesticated animals, very little is known concerning the life-history of the parasites, and nothing but supposition as to the means by which their hosts become infected. Further, a marked uncertainty or contradiction exists as to the power these parasites possess in producing a serious and recognizable disease.

It would appear that in the majority of cases of infection, in otherwise healthy animals, the invasion is a very limited and harmless one, involving to a more or less slight extent the muscles of the oesophagus and tongue, but that in certain conditions, generally of obscure origin, and briefly designated under the term 'cachectic,' the parasites may overrun the entire muscular system and become a grave menace to the life of their hosts.

A brief resumé of the more important observations on the subject by various authors is here given:

Nomenclature.

(a) Muscular Psorospermosis.
(b) The sarcocysts, tubes, sacs or utricles of Miescher.
(c) Rainey's corpuscles (the spores of the cysts).
(d) Sarcosporidiosis.

It is stated in Neumann's Parasites, that about 40 per cent of pigs may be infected. Moule, quoted by the same authority, found the parasites in 95 per cent of cachectic sheep, usually numerous in proportion as the cachexia is more accentuated. In 100 sheep in good condition he met with them in 14, and then always in small numbers. Of 100 oxen condemned for being in extremely bad condition he found 37 infected with Sarcosporidium. In cattle in good condition he found them only in three instances.

Schenze noted their presence in the muscles of the forehead of a horse, destroyed on account of paralysis of the anterior limbs. Some similar examples are also recorded by Neumann. The following extracts are quoted from Minchin's account of the Sarcoptidium:

In acute cases all the skeletal muscles may be infected, even those of the head. the parasite grows until it distends the fibre to four or even ten times its normal breadth absorbing the contractile substance as it does so. . . . The cysts are observed to degenerate in some cases, their adventitious walls becoming calcified, in other cases the cysts burst and spread their contents in the surrounding tissues, destroying the musclos and producing tumors and abscesses.

The symptoms of Sarcoptidium in the pig are paralysis of the hinder extremities, a skin eruption, and general symptoms of sickness, such as thirst, increased body-temperature, and dim, streaming eyes.

The disease is sometimes the cause of fatal epidemics among domestic animals, especially sheep. In the mouse also Sarcocystis muris is a very deadly parasite. Laveran and Mesnil have isolated the toxin of the Sarcosporidium parasite of the sheep, and named it Sarcocystine, a substance found to be extremely toxic for the experimental rabbit.
From some feeding experiments by Smith and others, quoted by Minchin it seems extremely probable that infection naturally occurs through the digestive tract. Sarcosporidiae have rarely been found in man; a few cases of fatal infection are mentioned by Neumann, and others by Bullock. 

Osterberg does not consider the eating of flesh of infected animals dangerous to man. Neumann again thinks that infected meat should be prohibited for human use 'because of its bad appearance and diminished nutritive value.' According to the same author 'muscular Sarcosporidium is not betrayed during life by any appreciable signs and the parasites can be detected only at autopsy.'

The following cases have come under the writer's personal observation:

(a) In Cattle Suspected of Loco-poisoning.

Case I.—(Animal No. 27) heifer, 3 years old; said to have developed symptoms of loco-poisoning as a yearling.—(Dr. Hilton) Received at quarantine station October 27, 1907; stunted, undersized appearance, and in poor flesh; coat staring and rough, on passing hand over the body numerous small scurfy nodules could be felt, knots of hair united with moist, bran-like scales. There were frequent prolonged extensions of the head and neck, accompanied by a more or less constant trembling and agitation of the muscles of these parts, especially of the jaws and most marked during attempts at feeding. The power of the pretension of food being practically lost, and mastication very difficult and incomplete. Death occurred November 14, 1907.

Principal features of Autopsy.—Gelatinous infiltration, light yellow to an orange colour, of the connective tissues, lungs and kidneys. The inner covering of the brain, the pineal, very dark, almost black in places, and of a metallic lustre. The heart enlarged, appearing soft and flabby, yet proving tough on section. The endocardium sprinkled with minute whitish granules, very numerous.

Microscopic.—Heart and its endocardium very extensively infected with Sarcosporidiae. Unfortunately, by the time these preparations had been examined and the parasites recognised, the carcass had been disposed of, and none of the skeletal muscles preserved. There was an immense deposition of greenish brown pigment granules in the covering of the brain and the cells of the cortex.

Case II.—Heifer (animal No. 88). The symptoms and condition being so similar to Case I, they need not be further described, beyond adding that there was a thin watery discharge from the nostrils, dimmed eyes, and occasional lacrimation. After being under observation for three months, in which the disease made steady progress, until the animal became quite helpless, she was destroyed.

Principal lesions at autopsy.—Fibrinous inflammation of epicardium. Minute whitish specks showing through endocardium. The heart as a whole too voluminous.

Lungs.—Chronic, suppurative inflammation. Small sacs or cysts, about the size of a bean or small nut, and rather resembling lymph nodes, could be squeezed from the cut surface of the parenchyma. The appearance of the skeletal musculature slightly granular, dusky and light brownish-red colour. The brain in this case did not reveal any abnormalities visible to the eye. The molar teeth were very irregular and badly developed, and the bones of jaws and face thin and brittle, though rather enlarged.

Microscopic.—The following muscles, organs or tissues were examined for Sarcosporidiae. (1) Psosas, (2) diaphragm, (3) tongue, (4) larynx, (5) upper and lower lips, (6) the gums, (7) the jaws, mas-sero and buccal, (8) the muscles of the poll, splenius and complexus, (9) of the eye, (10) of the limbs, the adductor magnus, flexor pedis perforatus, flexor metacarpi externus, (11) the heart, (12) the liver, (13) spleen, (14) kidneys, (15) lungs. In every specimen of every muscle examined.
the parasites were exceedingly numerous; Plate I., figs. 1 and 2, representing the
degree of invasion. In the lungs the semi-purulent cysts consisted of leucocytes and
disintegrating cellular tissues; a few Sarcosporidiae in process of decay were seen. It
is extremely probable, but not proved, that these inflammatory areas in the lungs
resulted from the presence and disintegration of Sarcocysts. In the spleen, liver and
kidneys, a very few degenerating spores were seen and much granular pigment
matter.

The myocardium contained very numerous parasites. While, as already stated,
all of the skeletal muscles were extensively invaded, those of the head, poll and extremi-
ties were, if anything, the more heavily infected.

CASE III.—(Animal No. 83) Steer, 3 years old. Similar condition to preceding
cases, but the disease not so far advanced. During the past three months, in which
the animal had been hand-fed and well cared for, the symptoms have increased in
severity. Depression is deepening, muscular action stiff and slow. Jaws swollen.
The animal was cast and a small fragment of muscular tissue excised from the tongue,
Flexor Metacarpi Externus, the masseter, and one of the cervical muscles. Sarcosporidiae
were found in preparations of each, not as numerous as in cases I. and II., but still
fairly plentiful. The present condition of the animal leaves little chance for recovery.

CASES IV., V. and VI. = Animals 81, 85 and 86. Steer and two heifers, two,
three and two years old respectively. The condition is approximately the same in each,
namely, slow, sluggish muscular action, depression, an a dejected, unthrifty appear-
ance. These animals were cast and operated on as in Case III. The muscles examined,
and the results as follows:—

Case IV.—Masseter—Sarcosporidiae numerous.
Upper cervical—Sarcosporidiae fairly numerous.
Tongue—Sarcosporidiae numerous.

Case V.—Flexor metacarpi externus—Sarcosporidiae not found.
Middle cervical—Sarcosporidiae fairly numerous.
Tongue—Sarcosporidiae very numerous.

Case VI.—Lower cervical—Sarcosporidiae numerous.
Tongue—Sarcosporidiae numerous.

Thus in all muscles examined, with the single exception of a very small frag-
ment of the flexor metacarpi, Sarcosporidiae were present.

(b) In the Equines Suspected of Loco-poisoning.

CASE VII.—(Animal No. 91.) Gelding, rising 3 years old showing symptoms of
loco-poisoning as a yearling.—(Dr. Hilton.)

The condition, briefly, on admittance to the quarantine station, October 27, 1907,
depression, restlessness; slowly wandering about without aim or object. Slow, high,
habitually gait, as if walking over obstacles. When disturbed, the head is carried
very low, down to the level of the knees, the neck often twisted. When suddenly
startled, there is a brief period of excitement and the animal may stagger and fall.
At present date, after a period of five months, the condition has become greatly
aggravated, and it does not look possible for the animal to live much longer. Flexion
and extension of the limbs are extreme, and brought about very slowly, and it is
quite impossible for the animal to run, trot or move out of a slow walk. The bones
of the face appear much swollen, and the expression truly melancholic and pitiable.
Small sections of the tongue and masseter muscle were removed and Sarcocysts were
found in micro-sections of each. The parasites were few in number, and small,
though containing spores.
CASE VIII.—(Animal No. 93.) Gelding, rising 3 years old, also showing symptoms of loco-poisoning as a yearling. On October 27, 1907, the condition was very fair, symptoms only slightly noticeable; but during the past five months the disease has greatly advanced until the present condition is quite as bad as the preceding case. A fragment of the flexor metacarpi externus muscle only has been examined. Sarcocysts were present, few in number, and in a young stage of growth. Previous to the finding of Sarcosporidiaceae in any of the foregoing cases, five loco-diseased equines had succumbed. The parasites not being suspected none of the skeletal muscles were microscopically examined. A portion of the myocardium was preserved in each case, in which no parasites were detected. A section of the tongue of one of these animals had been preserved, and in this Sarcosporidian cysts were found.

(c) In Dourine-affected Equines.

CASE IX.—(Filly, 9 months old.) Experimentally infected with Trypanosoma Equiperdum. In the fluid of a cutaneous swelling that followed the inoculations free spores of Sarcocysts together with trypanosomes were found, each species of parasite being present in about equal numbers.

CASE X.—(Filly, 2 years old.) Inoculated with the blood of a Dourined stallion. Seven months later, in the fluid of a cutaneous swelling, free Sarcocysts were present, mostly crescentic forms, and indistinguishable from the crescents described by certain authors (see Plate II.) as developmental forms of Trypanosomes. Trypanosomes were not seen in this animal at this time.

CASE XI.—(Mare, 3 years old), in fatal stages of naturally acquired Dourine. Sarcocysts were found free in the fluid of a swelling on two occasions, the swellings resulting from some serum-injection experiments.

(d) In a Cachetic Filly, the Cause of the Cachexia Not Known.

CASE XII.—(Filly, 2 years old), one of six supposedly healthy fillies shipped to quarantine station for experimental work. It was noted on arrival, that this animal (No. 68) had an unthrifty appearance, stiffened gait, rough hide and was in poor flesh. The mucous membranes were pale. She was several times carefully examined for signs of Dourine, but none were detected. The cachexia became more evident during the autumn and winter, with increasing stiffness of the muscle and gait, especially of the hinder extremities. The animal was found dead in the pasture on March 4th last, the body frozen.

The muscles of the oesophagus, tongue, and extensor of the fore-arm were infested with Sarcosporidia. They were not seen in the myocardium or the muscle of the eye; none other were examined.

In cases I. to VIII. of Sarcosporidiosis in 'locoed' animals certain symptoms and conditions are described. These are more or less characteristic of 'loco-disease.' This disease itself is now under investigation at this station and will be the subject of a separate and later report, and is only mentioned here in those respects in which it may bear a possible relation to Sarcosporidiosis, or where the writer is unable to differentiate between the symptoms of the one and the other. Certainly, a great variety of conditions and symptoms occur in the course of the malady or maladies attributed to loco-poisoning. There appear various forms of mental derangement, from mania in the first stages to a dense stupor or comatose condition in the latter; disorders of the muscular system from increased reflexes to spasm, atrophy and paralysis; osseous enlargement or degeneration, especially of the jaws and parts of the skull; impaired vision; depravity, enucleation, &c. The history in most cases shows that the disease is very chronic, and often of a fluctuating or intermittent character. The muscles of the head and neck, especially of the jaws, the lips, and the tongue exhibit tremors, spasmodic contractions or prolonged after-contractions. The
jaws sometimes remain rigid, the head and neck extended. In equines cramps are not infrequent, a limb is slowly extended as far as possible, remaining in that position for a short time, then slowly and extremely flexed, held high above the ground for a minute or more, the animal moving off at a lope. The contractility of the muscles is delayed, slow, and hesitating, not arrested at the proper moment, resulting in overflexion and extension. This might be explained by absorption of pressure on, or breaks in the continuity of the protoplasma of the muscle fibres by the Sarcocysts, and consequently, a greatly reduced conductivity. It is equally true, that the origin of this muscular disturbance may be seated in the nerve cells of the brain, as a result of loco-poisoning. If the latter hypothesis is correct, it is a strange coincidence that in the few cases examined the muscles most affected were those in which the parasites were most numerous. It is difficult to trace any relationship between the disease of the osseous structures of the jaws and face and the disease of the muscles; and yet, as mentioned before, Laveran and Mesnil isolated an extremely active poison from the Sarcocystis-tenella of the sheep (unfortunately, the original publication by these savants is not a hand) and it is permissible to assume that a similar toxic is elaborated by the parasites infecting the ox and horse. Sarcosporidiae appear more numerous in 'beefed' oxen than in horses; in the latter intestinal parasites are exceedingly plentiful, and very formidable-looking verminous aneurisms have been found at each autopsy. The condition favourable to these parasitic invasions may very likely originate from ingestion of the loco-weed, and possibly to some other dietetic conditions peculiar to the ranges where loco-disease prevails. It might be mentioned in passing that the writer has on several occasions examined specimens of meat, purchased from a local butcher, for Sarcosporidiae. In all, three ox-hearts, an ox-tongue, and several joints of beef have been examined, each specimen being from a different animal. Of these only one was found infected with Sarcosporidiae, a heart, the parasites being very numerous. This heart looked decidedly unhealthy. There were a few fibrinous growths on the epicardium, considerable gelatious column, and the little fat remaining, very soft and yellow.

Concerning the Parasite, Sarcocystis.

Class—Sporozoa; sub-class—Neosporidiae; Order—Sarcosporidiae; Genus—Sarcocystis, Ray Lankester. (After Minchin.) Infecting domestic animals there are probably several distinct species of Sarcocystis, but these have not been clearly differentiated.

In those infections of the horse and ox, already described, and even in the most heavily infected cases, very young forms of parasites could never be found; only the trophic phase was met with, accompanied by spore-production, as in all of the sub-class of Neosporidiae. In cattle the youngest trophozoites observed were lodged in the muscle fibre, and, though microscopically invisible, had attained a considerable size and formed several hundred spores. The larger parasites, distending the muscle fibres, are just visible to the naked eye as minute whitish rods or specks. In the equines, Cases VII. and VIII., the parasites averaged a much smaller size than in the bovines, the smaller trophozoites containing only the spore mother-cells or parasporoblasts, preliminary to sporulation. In these young forms the radially striated enveloping membrane is well marked (Plate I., fig. 3); as the parasite matures the membrane becomes thinner and the striations disappear, until, in the largest forms as seen in cattle, the parasite appears to be held only by the sarcolemma of the muscle fibre. Evidently the parasites are able to multiply within the body of their host until every part of the muscular system is invaded; this endogenous mode of infection is hypothetically brought about by rupture of the cysts and dissemination of the spores, and yet, if this is actually the case it is strange that even in such severely infected cases as I. and II., no intermediate forms between the relative minute spore and large young trophozoite could be found.

The spores themselves, the elamydospores, vary considerably in shape, size, and
in the arrangement of their chromatin and polar capsule. In form they appear in all
gradations from a perfect sphere to an oval, bean-shaped or crescent form, though
each type is symmetrical and doubtless represents different stages in the development
of the spore-cell. The spherical forms would appear to be the younger and the crescentic
the older, as in each trophozoite containing many spores, some are found dis-
integrating and these are almost invariably of a crescentic variety.

The chromatin granules of the nucleus of the spherical spore are relatively small
and scattered, and the polar capsule is granular and only partially developed; in
the next stages, the chromatin collects into small bodies, and one end of the cell
becomes pointed, and at this end is always found the polar capsule. This capsule
stains with difficulty with most dyes, and not at all with the ordinary basic
stains; even with some of the Romanowsky preparations only a faint pink ectoplast
at one end of the spore, and where the protoplasm has receded, denotes the position
of the capsule (see Plate II., fig. 3, No. 6). The Romanowsky stains, however, are
preferable to any other, and, properly prepared, differentiate very clearly and beauti-
fully the structures of the cell. A single granule, staining black, and, more rarely a
double granule, may occasionally be seen, situated about half-way between the nucleus
and the pointed extremity; this is doubtless the centosome. (Plate II., fig. 7—the
end spore, fig. 3, Nos. 1 and 6). In the older spores the nuclear chromatin collects
into round or irregular bodies, eight to sixteen in number. The frequent finding of
a large spherical spore and a crescent lying intimately, and in some cases apparently
fused, together, is suggestive that the former is the female cell and the latter the
male gamete (Plate II., fig. 3, No. 5). A large spherical form, probably resulting
from the fusion of these two elements, may be seen dividing directly into two, three
or four. (Plate II., figs. 2 and 3).

The possibility of mistaking the spores of Sarcocystis for developmental forms of
Trypanosomata.

From time to time mention is made by various workers, of large ‘crescentic
bodies’ or ‘vermicule-like forms’ occurring in the blood of animals affected with
trypanosomiasis, and are generally described as developmental stages in the life-
history of a species of trypanosomata.

Holmes, in an article entitled ‘Trypanosomiasis among cattle in India,’ states,
‘In the blood taken from two infected bulls I found peculiar developing forms bear-
ing a striking resemblance to the crescents of human tertian fever. These are large
crescent-shaped bodies staining blue and containing numerous chromatin granules.’
Some of these forms of trypanosomata (1) are illustrated by author.

Lingard® in ‘Species of trypanosomata observed in Bovines in India’ mentions
the above observations of Holmes, and further describes similar forms met with by
him (Lingard), also illustrating them in coloured plates (Plate II., fig. 20, and Plate
III., fig. 7, Journal Tropical Sci. Vol. II., No. 7, 1907), stating ‘These cres-
cent forms, above described, are frequently co-existent with the piroplasma bigeminum,
or the smaller forms in the blood of Indian cattle. Possibly the presence of the cres-
cents in Queensland bovines may point to the fact that these animals in some instances
are also the host of a large form of trypanosoma, which up to the present has not been
demonstrated in their blood.’ Hunt, quoted by Minchin (page 269) and also by
Lingard, ‘found crescents in the blood of cattle, and observed their change into a
spheroideal shape, but while comparing these bodies to the crescents of malarial
parasites, he at the same time regards them as a form of sporulating body, producing
spores endogenously.’ Martin in criticizing the observations of Holmes states,
‘Raymond also afterwards found them (i.e., the crescents) in the cattle of Bengal,
and he is inclined to the opinion that they have nothing to do either with trypano-
osomiasis or piroplasmosis, but that they are really Sarcosporidia.’ The writer ventures
to express a similar opinion. At first, in finding them in the cutaneous swellings of
Dourine-affected equines, side by side with mature and unmistakable trypanosomes,
PLATE 1.

Fig. 1.

Fig. 2.

Fig. 3.
and after a careful comparison with the illustrations and descriptions furnished by Holmes and Lingard already referred to, and to which they appeared identical, he was inclined to consider them as developmental forms of trypanosomata. But subsequently, when positively no difference could be detected between these forms and certain of the spores of Sarcocystis isolated from cases I. to VIII. and case XII., he (the writer) became convinced that they belong to the latter genus of a parasite, and excludes any relationship between these crescents and trypanosomata. Certainly, such forms of the spores of Sarcocystis as are here depicted, Plate II., fig. 5, Nos. 2 and 6 and some others, may very easily be mistaken for trypanosomes in which the flagella and undulating membrane have been cast off, for 'stumpy,' swollen forms. It is of great importance, therefore, in diagnosing such a serious infection as Trypanosomiasis from blood specimens to remember the possibility of the presence of Sarcosporidia and their likeness to questionable forms of trypanosomata.

Conclusions.

1. The parasite Sarcocystis under certain conditions becomes a very important factor in disease, invading the entire musculature of their host, with serious or fatal consequences.

2. Sarcosporidiosis may be closely associated with, and is probably a very frequent sequel to, the disease of horses and cattle known as 'Loco-disease.' It may complicate the diagnosis of this disease, and also of Leptinera, and probably of some others, and retard or prevent recovery from these and similar ecdylic conditions.

3. The crescentic spores of Sarcocystis bear a striking resemblance to 'Crescentic-bodies' that have been described as developmental forms of trypanosomata, and it would be unsafe, or quite erroneous to diagnose an infection by the latter from the presence alone of these crescentic bodies.

4. The Sarcosporidiae are deserving of more detail study and investigation than has hitherto been accorded them, both from a zoological and a pathological standpoint.

EXPLANATION OF PLATES.

Fig. 3. No. 6.—An example of spores more lightly stained, and showing only the position of the polar capsule.
Fig. 4. Nos. 1-6.—Constriction of the protoplasm, and extended bodies (1), No. 4, suggesting that the pointed extremity of the crescent spore had penetrated one of these bodies.

Fig. 1-4.—Are taken from Sarcosporidiae of the ox.

Fig. 5.—Represents types of spores found free in the fluid of cutaneous swellings in dourine-affected equines.

All figures in Plate II. are stained by the writer's modification of the Romanowsky method, prepared as follows:—A polychrome blue is made by one per cent solution of medicinal methylene blue in a one-half per cent aqueous solution of sodium bicarbonate, heating and evaporating to dryness over a water bath. The residue is powdered and two solutions then prepared—

A.—35 ccm. B. 4 ccm. in 16 ccm. of methyl alcohol.

B. 0.5 per cent eosin in methyl alcohol and mixed in the following proportions:

A.—35 ccm. B. 4 ccm. in 16 ccm. of methyl alcohol.

This solution is slightly alkaline (very useful for some purposes) for the study of Haematozoa and Sarcosporidiae. A drop or two of an exceedingly dilute solution of acetic acid in alcohol should be added, care being taken not to over neutralize, and the stain applied as in Leishmann's and other alcoholic Romanowsky stains.

The proportions of A and B may be varied slightly increasing the amount of Eosin according to the reaction desired, and the stain may also be further diluted with methyl alcohol to advantage.
